Abstract

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata
Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

DTAs are highly sparse (most transitions are undefined), equivalence of states depends on multiple inputs, and care must be taken in order to minimize them efficiently. We fully describe a simple implementation of the standard minimization algorithm that needs a time in $\mathcal{O}(|A|^2)$.

DTA as compact data structure/1

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata
Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

Minimal DTA can store (unranked ordered) tree data efficiently:

- 1 Each subtree which is common to several trees is assigned a single state.
- 2 A single state is assigned to groups of subtrees that may appear interchangeably in the collection.

Congruences in DTA

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs

Minimal automata

Signatures

Accessibility

Algorithms

Description

Analysis

Results

Experiments

Conclusions

In a minimal DTA $p \equiv q$ implies

$$p \in F \leftrightarrow q \in F$$

and for all $m > 0$, all $k \leq m$ and all $(\sigma, r_1, \dots, r_m) \in \Sigma \times Q^m$

$$\delta_m(\sigma, r_1, \dots, r_{k-1}, p, r_{k+1}, \dots, r_m) \equiv \delta_m(\sigma, r_1, \dots, r_{k-1}, q, r_{k+1}, \dots, r_m)$$

DTAs vs DFAs

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs

Minimal automata

Signatures

Accessibility

Algorithms

Description

Analysis

Results

Experiments

Conclusions

Compared to DFAs, DTAs

- Lack initial states (transitions with $m = 0$ as $(a, 1)$ and $(b, 1)$ are used as seeds).
- Transitions depend on m states (all siblings).
- Are highly sparse (there are n^m possible inputs of size m , n is num. states).

DFA minimization/1

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata
Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

- DFAs can be minimized in time $\mathcal{O}(kn \log n)$ (k is alphabet size).
- Customary initialization is $\mathcal{O}(|A|^2 \log |A|)$ for sparse DFA.
- A suitable finer initialization leads to $\mathcal{O}(|A| \log |A|)$ cost.

DFA minimization/2

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs

Minimal automata

Signatures

Accessibility

Algorithms

Description

Analysis

Results

Experiments

Conclusions

Standard DFA minimization builds the partition $P_0 = \{F, Q - F\}$ and a coarse transition function for all $I, J \in P$:

$$\Delta_{IaJ} = \{(i, a, j) \in \Delta : i \in I \wedge j \in J\}$$

Whenever $s = |\Delta_{Ia}| > 1$, I is split into s classes.

- Finding such (I, a) and updating Δ_{IaJ} is $\mathcal{O}(n)$.
- Number of iterations is $\mathcal{O}(n)$.
- Complexity $\mathcal{O}(kn \log n)$ requires that the largest I subset (that with largest Δ_{IaJ}) remains as I .

Signatures/1

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata

Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

Sparse DFA require:

- Identify useless states and collapse them to \perp .
- Initialize the partition P with subsets of states with identical signature and class (accepting or not).

The *signature* of q is

$$\text{sig}(q) = \{a \in \Sigma : \exists(q, a, p) \in \Delta\}$$

Then, only defined transitions are checked.

Signatures/2

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata

Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

In a DTA different definitions of signature are possible

$$\text{sig}(q) = \{\sigma \in \Sigma : \exists(\sigma, i_1, \dots, i_m, j) \in \Delta : \exists k \leq m : i_k = q\}$$

$$\text{sig}(q) = \{(\sigma, m) : \exists(\sigma, i_1, \dots, i_m, j) \in \Delta : \exists k \leq m : i_k = q\}$$

$$\text{sig}(q) = \{(\sigma, m, k) : \exists(\sigma, i_1, \dots, i_m, j) \in \Delta : \exists k \leq m : i_k = q\}$$

$$\text{sig}(q) = f(\{(\sigma, i_1, \dots, i_m, j) \in \Delta : \exists k \leq m : i_k = q\})$$

Homomorphism f is:

$$f(i_k) = \begin{cases} * & \text{if } i_k = q \\ 0 & \text{if } i_k \neq q \wedge i_k \notin F \\ 1 & \text{otherwise} \end{cases}$$

Our implementation works with all definitions.

DTA minimization/1

DTA coarse transition function

$$\Delta_{\sigma l_1 \dots l_m J} = \{(\sigma, i_1, \dots, i_m, j) \in \Delta : i_1 \in l_1, \dots, i_m \in l_m, j \in J\}$$

If $s = |\Delta_{\sigma l_1 \dots l_m}| > 1$ at least one l_k needs split. However:

- It is possible that more than one l_k needs split.
- Different $l_{k'} = l_k$ may lead (partially) to same subclasses.
- Which is the largest subset in l_k has nothing to do with the number of transitions in $\Delta_{\sigma l_1 \dots l_m J}$ (the other l 's play).

Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

Useful properties:

- Equivalence is transitive: we define $\text{next}_n(q)$ to return next (or first) element in the equivalence class.
- If two states are not equivalent there exists a pair of distinguishing transitions and at least one leads to $q \neq \perp$.

Graphical interpretation: at least one red-to-blue transition.

Accessible and coaccessible states/1

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata
Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

Some definitions:

- State q is *inaccessible* iff $L_A(q) = \emptyset$.
- Accessible state q is *coaccessible* iff there exists $t \in L(A)$ with a subtree s such that $q = A(s)$.
- States which are not coaccessible (and accessible) are *useless*.

For instance, the absorption state \perp is accessible and useless.

Accessible and coaccessible states/2

An implementation of deterministic tree automata minimization

RC Carrasco
J Daciuk
ML Forcada

Introduction

DTAs
Minimal automata

Signatures
Accessibility

Algorithms

Description
Analysis

Results

Experiments
Conclusions

Accessible states can be found with bottom-up procedure and useless states with a top-down one.

For instance, if $F = \{2\}$ with the computation

- 1 makes 2 accessible,
- 2 makes 1 coaccessible.

Input: A DTA $A = (Q, \Sigma, \Delta, F)$

Output: The subset of inaccessible states in A .

- 1 For all q in Q create an empty list R_q .
- 2 For all $\tau_n = (\sigma, i_1, \dots, i_m, j)$ in Δ do
 - $B_n \leftarrow m$ [Num. of inaccessible pos. in $\arg(\tau_n)$].
 - For $k = 1, \dots, m$ append n to R_{i_k} [Occurs in i_1, \dots, i_m].
- 3 $K \leftarrow \{\delta_0(\sigma) : \sigma \in \Sigma\}$; $I \leftarrow Q - K$
- 4 While $K \neq \emptyset$ and $I \neq \emptyset$ remove a state q from K and for all n in R_q do
 - $B_n \leftarrow B_n - 1$
 - If $B_n = 0$ and $\text{output}(\tau_n) \in I$ then move $\text{output}(\tau_n)$ from I to K . [Whole argument accessible]
- 5 Return $I - \{\perp\}$.

Experiments
Conclusions

Input: A reduced DTA $A = (Q, \Sigma, \Delta, F)$ with $F \neq \emptyset$.

Output: The subset of useless states in A .

- 1 For all q in Q create an empty list L_q .
- 2 For all $\tau_n = (\sigma, i_1, \dots, i_m, j)$ in Δ add n to L_j
[Store n such that j is the output of τ_n (kind of Δ^{-1})].
- 3 $K \leftarrow F$; $U \leftarrow Q - F$
- 4 While $K \neq \emptyset$ and $U \neq \emptyset$ remove a state q from K and for all n in L_q and for all i_k in $\{i_1, \dots, i_m\}$ do
 - If $i_k \in U$ then then move i_k from U to K .
- 5 Return U .

Input: a DTA $A = (Q, \Sigma, \Delta, F)$ without inaccessible states.

Output: a minimal DTA $A^{\min} = (Q^{\min}, \Sigma, \Delta^{\min}, F^{\min})$.

- 1 Initialize partition P and queue K .
- 2 Main loop (refine P).
- 3 Output A^{\min} .

Notation:

- P_n is the partition at iteration n .
- $[q]_n$ is the equivalence class of q in P_n .
- $p \sim_n q \leftrightarrow [p]_n = [q]_n$.

Experiments
Conclusions

- Remove useless states from Q and transitions using them from Δ and set $Q \leftarrow Q \cup \{\perp\}$ and $n \leftarrow 1$.
- For all $(\sigma, i_1, \dots, i_m) \in \Delta$ add (σ, m, k) to $\text{sig}(i_k)$ for $k = 1, \dots, m$.
- For all $q \in F$ add $(\#, 1, 1)$ to $\text{sig}(q)$. [include acceptance in signature]
- Create an empty set B_{sig} for every different signature sig and for all $q \in Q$ add q to set $B_{\text{sig}(q)}$.
- Set $P_0 \leftarrow (Q)$ and $P_1 \leftarrow \{B_s : B_s \neq \emptyset\}$.
- Enqueue in K the first element from every class in P_1 .

Algorithms

Description
Analysis

Results

Experiments
Conclusions

- Simple and efficient minimization of DTA is possible: the search for inconsistent classes can be efficiently performed and undefined transitions and the absorption state can be properly handled.
- A better asymptotic behavior may be still possible.
- We are studying incremental minimization of DTAs (minimization of a partially minimized automaton).
- Incremental construction (construction of a minimal DTA by adding new trees to the language accepted by an existing one) has also been addressed.
